

	P1	P2	P3	P4	P5
1. Interaction context. How the kind of situation does the platform have to notice P1b?	Smart Shuffle on Spotify is the dominant decision context across both weeks, and the participant uses the same decision-making strategy. Reels form a secondary context, encountered passively during casual scrolling. Spotify is used as a music discovery instrument, where the music is resisted and minimized, and this contrast in attentional mode distinguishes the two platforms. While Spotify promotes behaviors surface through a feature-epistemic mismatch, the gap between what Smart Shuffle claims to do and what it actually does is the mismatch, and the participant scrolls into different content and interacts with the default detection menu in Clara's persistent appearance. The participant is not interested in the accumulated exposure.	Problematic behaviors surface across multiple platforms and contexts: i) Instagram's reels, which present a false narrative of aesthetically similar artists makes the lack of diversity immediately apparent; ii) Apple Music's social listening instrument, where the participant following a specific song reveals identity-based placement patterns; and iii) TikTok's neuromusic aesthetic, where the participant's algorithmic feed delivers mainstream content misaligned with the participant's tastes. This mismatch prompts the participant to resist the music, and the participant scrolls into different content and interacts with alternative video to test the algorithm.	Problematic behaviors surface primarily during auto-continuation after actively searching for a specific song, where the queer shifts unexpectedly across genres. Mainstream platforms are used instrumentally, for comfort, low ad interruption, and social listening. While SoundCloud is reserved for deliberate independent discovery, and this platform switching is a conscious and habitual strategy that predates the study, the classical music case reveals an additional context, where long and uninterrupted listening triggers cross-context recommendations, and the participant's algorithmic listening mode and duration shape what the algorithm surfaces.	Problematic behaviors are noticed primarily in two situations: i) post-playlist autoplay continuation, where the participant's algorithmic feed switches across genres; ii) homepage browsing, where promoted artists appear without contextual relevance. The participant deliberately uses the liked songs playlist as a discovery context, expecting higher-quality recommendations from it. It is the participant's algorithmic feed that is responsible for checking what comes next that makes commercial insertions visible, and the participant explicitly notes the participant's algorithmic feed that is responsible for checking what comes next that makes commercial insertions visible.	Problematic behaviors surface across multiple contexts: i) homepage browsing, ii) daily mix and social listening, and iii) autoplay continuation. The participant's algorithmic feed is responsible for checking what comes next that makes commercial insertions more visible. In particular, the K-pop daily mix case shows that the participant's algorithmic feed that is responsible for checking what comes next that makes commercial insertions more visible. In particular, the K-pop daily mix case shows that the participant's algorithmic feed that is responsible for checking what comes next that makes commercial insertions more visible.
2. SB reasoning. How does the participant perceive social bias in recommendations?	Social bias is noticed on Instagram but not on Spotify. The central claim is that Instagram recommends female artists not because they are musically relevant but because they are visually appealing to a male user, meaning the algorithm targets gender-based appeal. This is supported by the observation that male artists almost never appear in the feed despite the participant listening to mostly male artists. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Social bias is a salient dimension for this participant, who noticed both male-dominated and female-dominated recommendations depending on the platform, and this is interpreted not as opposing problems but as the same underlying mechanism. On Instagram only women appear, on TikTok's neuromusic only men appear, and on Apple Music recommendations are organized around male artists. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Social bias is not a salient dimension for this participant and receives no dedicated attention across either study weeks. The interview, the SB diary prompt did not trigger observations about gender, ethnicity, or cultural diversity, with responses shifting attention toward genre mismatch and commercial promotion. This absence is notable given a listening profile that spans multiple genres. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Social bias is a salient dimension for this participant, who noticed both male-dominated and female-dominated recommendations depending on the platform, and this is interpreted not as opposing problems but as the same underlying mechanism. On Instagram only women appear, on TikTok's neuromusic only men appear, and on Apple Music recommendations are organized around male artists. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Social bias is the least salient dimension for this participant and is consistently attributed to the participant's own listening habits. A recurring framing describes the prevalence is noticed but explained through sociology. Electronic and EDM scenes are historically male-dominated, and this is known to the participant. The participant explicitly declines to attribute to the platform patterns attributed to the participant's own listening habits. The participant introduced the intersection of gender and nationality, where Italian artists in some electronic subgenres are overrepresented. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."
3. CI reasoning. How does the participant explain logical reasoning in recommendations?	Commercial causation is less in uncertainty than algorithmic causation. The participant is committed, feeling like they are taking a risk, to committing fully to either algorithmic or commercial explanation. The language used, such as "algorithmic causation," implies a methodical, implies commercial exploitation, but a detailed structural account of label-platform mechanisms is not developed. The identified pattern of the platform is not doing what it claims to do, experienced as a form of dishonesty toward the user. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Commercial logic is identified consistently but held in uncertainty. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Commercial logic is the primary and largest explanation. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Commercial logic is clearly identified and explained. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Commercial logic is identified clearly and connected to the participant's algorithmic feed. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."
4. LD reasoning. How does the participant experience and explain discovery constraint?	Discovery constraint is the dominant and most emotionally elaborated dimension. Smart Shuffle produces one unknown song in fourteen days of the study, and the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Discovery constraint is experienced as confinement within a specific aesthetic, the "estetica" framing, not just genre repetition but a broader convergence of aesthetic elements. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Discovery constraint is experienced as a cycle of genre incoherence. The algorithmic groups songs by familiarity rather than by genre proximity, producing unexpected results. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Discovery constraint is experienced as a cycle of discovery artists. Artists listened to infrequently are overrepresented in recommendations relative to those listened to frequently, suggesting the algorithm anchors on historical listening. The daily recommendation sections remain static for up to ten days, and the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Discovery constraint is experienced as a combination of platform repetition and personal habit. The participant acknowledges being a very repetitive listener, and the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."
5. Algorithmic attribution. How the platform and how does the participant assign agency to the algorithmic causation?	Algorithmic causation is less in uncertainty throughout, with oscillation between algorithmic and commercial causation. The participant is comfortable acknowledging when the algorithmic causation is the most responsible, with the Elettra Lamborghini case as the clearest expression of this. The most analytically interesting moment is the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Most events reflect ambivalence between algorithmic and commercial explanations. An attribution experiment reveals that the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	The participant actively theorizes about how the algorithm works, modeling collaborative filtering and social listening. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Algorithmic causation is consistently and deliberately decentered. Commercial promotion is the dominant explanation. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	The participant acknowledges having possibly over-attributed events to the algorithm due to uncertainty. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."
6. Platform relationship. How does the participant relate to the platform, and how does this change over time?	Continued use is justified by convenience and ecosystem integration across the phone, the computer, and PlayStation. Alternatives have been considered but dismissed on the grounds that other platforms are not as integrated. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Platform exposure is more rigid and crystallized, suggesting the participant's tracking algorithmic behavior across platforms. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Mainstream platforms are used for their convenience, low ad interruption, and social accessibility with others. SoundCloud is the preferred platform for genuine discovery and niche listening. This differentiated platform strategy was presaging and not produced by the study, as the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Continued use is unquestioned but experienced as increasingly static. The relationship with the platform is shaped by a recognized mutual fit between habitual listening tendencies and the platform's algorithms. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Trust visibly declined across the study period, explicitly stated in the diary entries and elaborated in the interview. Before the study the platform was used habitually without critical attention. The study revealed that the participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."
7. Perceived harm. How does the participant understand the consequences of algorithmic causation?	Harm is framed at two levels. At the individual artist level, unknown and less famous artists are structurally invisible, and only the discovery path to active engagement is available. At the community level, passive users are particularly vulnerable to algorithmic confinement, with the artists' harm being exacerbated by their consumption practices described as "sadd". Harm is framed as a structural disadvantage to artists and as a reduction of cultural diversity for listeners, connecting individual platform behavior to broader societal effects.	Harm is perceived clearly and with emotional engagement. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	Harm is framed as systemic and persistent. The Spotify algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."	The platform makes it easy to discover already popular artists and to find new artists without independent or emerging artists to gain visibility. Harm is framed as driven by the same commercial logic that motivates the platform's recommendations. The concrete proposal for an emerging artist's section is directly motivated by this harm perception.	At the artist level, emerging and niche artists are identified as static. The participant's algorithmic feed is modeled, starting with gender-based targeting for new accounts, and then critiqued for its failure to solve female representation. The participant does not suggest them to be because they're singing, you're not suggesting them to me because they're singing anything, they're singing "the sharpest statement of this argument."

	P8	P9	P16	P14	P6	P4	P20	P2	P5
8. Algorithmic awareness. What level of awareness does the participant bring to their interaction with the recommendations?	Awareness is moderate and preexisting, with the study deepening it. The participant came in already aware that Smart Shuffle was supposed to facilitate discovery and that it was failing to do so. Awareness moments concern the negative inference from algorithmic incoherence, recommendations too mismatched to be algorithmic, and the Instagram gender-targeting model. The understanding that algorithm pitch processes function for non-major artists is evident before the study began. The study deepened this awareness primarily by prompting inspection of queue details and the discovery of the editorial disclosure mechanism. The participant generates and then discards hypotheses, initially considering data insufficiency as an explanation for the YouTube Music anomaly, then ruling it out on evidence.	Awareness developed during the study from a low baseline, with the participant explicitly stating that the study allowed observation of platform behavior never previously attended to. A key awareness development is the theorization of user archetypes as an algorithmic design choice, which goes beyond simply noticing repetition. An understanding of differential platform responsiveness also develops, comparing how Instagram crystallizes while YouTube adapts, and of the role of sharing behavior as a stronger signal than passive viewing. The participant notices that interacting with alternative content did not change the feed, and hypothesizes that message sharing carries more algorithmic weight than viewing.	The participant came into the study with an already formed sense that recommendations were shaped by familiarity and engagement logic, and that some commercial insertions were present. The study deepened and made explicit a reasoning that had already been partially developed. The participant models how collective listening behavior shapes individual recommendations in the Sanremo case, and recognizes that the algorithm cannot know contextual facts like festival participation directly. The limits of skip signals as feedback mechanisms are also understood.	Awareness is high and explicitly predates the study by several years. The participant describes having noticed commercial insertions long before participating, and the post-study interview confirms the study refined the critical posture. Knowledge of platform distribution mechanics, pitch editorial processes, and geographic rollout strategies is demonstrated. The participant models how the algorithm categorizes music differently from personal listening preferences and uses this gap as analytical evidence for commercial insertion.	The study consolidated and made explicit a pattern the participant had partially noticed, the mutual reinforcement between habitual listening habits and the platform's repetition logic. Awareness moments concern cross-platform data inference and the distinction between algorithmic profile matching and commercial promotion. The "not interested" button mechanism and its practical limitations are also noticed. Awareness is growing but not yet technically elaborated.	Before participating, the platform was navigated habitually without attending to recommendation logic. The study produced what the participant describes as a new eye for algorithmic behavior, with recommendation sections now read analytically, static content noticed, and algorithmically and commercially driven suggestions distinguished. The participant identifies that the Women of Indie playlist was calculated based on the intersection of gender identity and genre preference, and that a user with identical genre preferences but a different gender identity would not receive it. Cross-platform data inference, questioning how Spotify could know about Netflix habits without account linkage, is a further marker of developing awareness.	The participant already knew they were a habitual listener before the study but had not applied critical attention to platform behavior. The study made algorithmic patterns visible that had been passively experienced. A distinctive awareness development is the inverse genre-labeling theory, that Spotify builds category labels around known artists. The "ripica" experiment demonstrates active algorithmic testing, and the assessment of Smart Shuffle reflects an understanding of how the feature defaults to popular content. The cross-platform promotion analysis around Sonar shows a capacity to trace multi-platform algorithmic dynamics.	Knowledge of how paid subscriptions reduce recommendation exposure, how cross-platform data sharing via Android notification reading works, and how editorial pitch processes function for non-major artists is evident before the study began. The study deepened this awareness primarily by prompting inspection of queue details and the discovery of the editorial disclosure mechanism. The participant generates and then discards hypotheses, initially considering data insufficiency as an explanation for the YouTube Music anomaly, then ruling it out on evidence.	The awareness that recent listening behavior shapes recommendations is clear, with indie disappearing from the feed when the participant stops listening to it. The tier-based feedback inequality reasoning is an awareness contribution arrived at independently through logical reasoning. A distinction is also drawn between content types in terms of recommendation logic, with podcast recommendations noted as more topic-specific while music recommendations are more genre-based. The participant explicitly acknowledges that the study shaped attention, and questions whether some observations were genuine events or study artifacts, a methodologically reflexive statement.
9. Discovery agency. How actively does the participant seek music, and how much effort do they feel discovery requires?	Within Spotify the participant relies on Smart Shuffle as the primary discovery mechanism, which proves largely ineffective. Active self-directed discovery, scrolling YouTube for recommendations and seeking out specific periods or genres, is identified as the only reliable alternative. The study itself functioned as a forced discovery exercise, and Smart Shuffle was continued specifically to generate material for registration, which incidentally produced one genuine discovery. Instagram is explicitly rejected as a discovery tool for music, with meme-mediated serendipity as the only occasional exception.	Platforms were deliberately reinstalled for the study, algorithm boundaries were actively tested, and peer networks, specifically Instagram stories and reels from followed accounts, are used as a more reliable discovery mechanism than other recommendations. YouTube functions as a genuine discovery platform when actively searching, and the participant plans to engage with Apple Music more strategically following the study. The participant also acknowledges their own role in reinforcing the loop through engagement, adding a reflexive dimension to the account of agency.	Listening is actively managed across multiple platforms according to their strengths, mainstream platforms for known music and social contexts, SoundCloud for genuine underground discovery. Strategies include listening to full albums, manually queuing songs, and using SoundCloud specifically for hyperpop discovery. Several new artists were discovered during the study period through platform suggestions, showing that mainstream recommendations occasionally deliver. Discovery effort is experienced as manageable but requiring deliberate navigation away from default recommendation behaviors.	Discovery is active and self-directed, where the liked songs playlist is deliberately used as a higher-quality discovery context, exploiting the observation that recommendations from that context are more accurate. Interpol was discovered during the study period, and a serendipitous genre crossing led to rediscovering RHCP. An explicit distinction is drawn between engaged listeners who invest time and effort in discovery and passive listeners who remain confined. Discovery is experienced as achievable but effortful, requiring deliberate platform navigation.	Discovery is low within the platform and relies primarily on external channels. Within Spotify the participant describes being genuinely lost when wanting to discover new music, as the mix sections repeat known artists and no other reliable discovery path is identified. TikTok is the primary and reliable discovery channel, with trends functioning as a serendipitous mechanism trusted more than platform recommendations. The proposal for a dedicated, accessible new music section is motivated by this personal need as much as by concern for artists.	Discovery is active and successful across both weeks. Agency is both reactive, responding to what the platform surfaces, and proactive, developing workarounds such as seeking artist-specific mixes and scrolling to the bottom of the homepage. The study itself became a discovery strategy, and playlists not normally listened to were opened to inspect their content, occasionally turning up relevant material. The artist-inspired mix format is identified as a more reliable discovery mechanism than default homepage recommendations, and platform use has been adapted accordingly.	Discovery is active and resourceful but bounded by habitual listening tendencies the participant explicitly acknowledges. Primary discovery strategies include user-generated playlists as alternatives to Spotify recommendations, TikTok show edit browsing as serendipitous discovery, and deliberate genre exploration on Spotify through specific searches. Paris Paloma and Mad Tsai were discovered during the study period. The "ripica" experiment is also an agentic act, deliberately testing whether changing listening behavior changes recommendations. The participant is aware that personal habits amplify the loop and makes deliberate efforts to counteract them, while acknowledging the difficulty of escaping them entirely.	The discovery workflow is deliberately segmented, with external sources such as DJ sets and concert recordings for initial discovery, platform research for passive verification and deepening, and personal curated playlists as the stable core. Web research, blogs, and specialist sites supplement platform recommendations when exploring a specific scene. The participant does not rely on algorithmic recommendations as a primary discovery mechanism and explicitly distinguishes this mode from the average listener's dependence on editorial playlists. Discovery is experienced as a circumscribed but attentive practice, with a clear awareness of when the participant is in discovery mode and when in maintenance mode.	Discovery is low within the platform and moderate outside it. The primary discovery event during the study, L'Officina della Camomilla, came from friends. Within Spotify the participant selects what the homepage presents, Smart Shuffle is not used, user-generated playlists are not sought as alternatives, and external sources are not used systematically. Agency is expressed primarily through avoidance, skipping unwanted songs. The participant is aware of this passivity and frames it partly as a personal disposition toward habitual listening.
10. Ethical framing. In what moral or systemic register does the participant evaluate problematic behaviors?	The dominant register is one of betrayal and dishonesty. The platform makes explicit promises, with Smart Shuffle described in its own UI as a discovery tool, and fails to keep them, experienced as a form of user manipulation in which users are instrumentalized as engagement metrics. For the participant, criticalities exist by design, and this means user feedback is structurally irrelevant absent competitive market pressure. The passive user vulnerability argument adds a harm dimension to the critique, as dishonesty toward the platform disproportionately affects those least equipped to seek alternatives.	There is a broad systemic critique connecting platform engagement logic to consumerism as a social phenomenon. The "poco meritocratic" framing is the most explicit statement, that the system rewards commercial viability, and the participant connects this to a wider social pattern of consumption-driven value systems. The framing situates platform behavior within a broader critique of how digital economies reproduce consumer society logic. The "disarmante" reaction to the TikTok newmusic page carries emotional weight but is quickly absorbed into structural analysis. The participant partially understands and even accepts the platform's simplification logic, adding a nuance of ethical ambivalence in which critique coexists with comprehension.	Platforms promote popular content because it serves their engagement and advertising revenue objectives, understood as rational behavior. The observation that improving discovery for niche artists is simply not in platforms' commercial interest is framed as a structural constraint. The Sillyvelly anecdote carries an implicit ethical charge, as the invisibility of independent artists on mainstream platforms is described as a problem worth naming, but it is not articulated in explicitly moral language. Ethical concern is present but subdued, expressed through structural analysis.	Platform problematic behaviors are understood as rational outcomes of commercial incentives, and are unlikely to change absent competitive market pressure. Structural pessimism runs throughout, and the participant notes that an emerging artist section will not be implemented because there is no economic interest in doing so. User feedback mechanisms are valued only if functionally effective, and purely symbolic feedback is dismissed as pointless. The critique is present, expressed through systemic analysis.	The dominant register combines platform accountability with commercial critique. The "contentino" framing, that platforms give niche content a token presence at the bottom of the page knowing it will not be engaged with, is an observation about performative diversity. Platforms do not promote artists without label backing because there is no financial return. Emotional engagement with the Chrissy Chapecka case gives the ethical framing a personal and affective quality, and the concern is directed at a specific artist the participant follows and values. The platform's influence is described as "liminante," a register that combines personal frustration with structural critique.	The personalized for you label on generic viral playlists is experienced as a false claim, with the platform asserting a level of personalization it does not deliver, and the participant frames this as a breach of honesty toward the user. Commercial economic logic is acknowledged as understandable but not accepted as justification. The participant recognizes why platforms promote certain content but argues this does not override the obligation to personally serve user preferences. The framing is interpersonal and trust-based, with the problem framed as the platform not keeping its implicit promise to the user.	The dominant ethical register combines personal contract violation, paying for premium creates an entitlement to genuine personalisation, with cultural critique, in that platform commercial logic homogenizes musical production. The participant theorizes that user feedback mechanisms risk only reaching already-sensitized audiences, producing resonance without reach, and proposes an in-platform peer-flaging system as a structural solution. This is a second-order observation about the limits of accountability mechanisms. The structural framing is present, but the personal engagement dimension, particularly around gender bias, gives the ethical register an affective quality.	The participant theorizes that better feedback could paradoxically help platforms construct more seamless commercial confinement, making problematic behaviors harder to detect. The absence of an external regulatory body for algorithmic recommendation choices is framed as a structural accountability gap. Non-transparency is the closest the participant comes to a moral evaluation, with deigning commercial promotion to appear organic described as deliberately deceptive, but even this is framed analytically. The ethical register is epistemically cautious, consistently flagging the speculative nature of structural observations.	The surveillance-as-care versus surveillance-as-exploitation distinction articulates why Spotify Wrapped feels different from advertising even though both involve data monitoring, locating the difference in the purpose and transparency of the data use. The tier-based feedback inequality observation carries an implicit ethical charge about differential treatment of paying versus free users. Normative platform design proposals, such as diversity-bridging playlists and user-controlled exposure percentages, are framed as ethical imperatives. The participant maintains throughout that the platform's mechanisms could be used differently and better, a structural critique expressed without moral indignation.
